1. General Directions

All reactions were performed under anhydrous conditions and an atmosphere of nitrogen in a 100 mL Mettler-Toledo Easymax[©] reactor or in a 500 mL ChemGlass reactor. Yields refer to chromatographically and spectroscopically (¹H-NMR) homogenous materials, unless otherwise indicated. Solvents and reagents: anhydrous MeCN, CH₂Cl₂, THF, Et₂O and toluene were obtained commercially from Sigma Aldrich[©]. ¹H NMR spectra: These were recorded at on a Bruker AV-400, AV-500 or AV-600 instrument. Chemical shifts (δ_{H}) are quoted in parts per million (ppm), referenced to the appropriate residual solvent peak. Coupling constants (J) are reported to the nearest 0.1 Hz. ¹⁹F NMR spectra: These were recorded at 376.64 MHz on Bruker AV-400 instrument. Chemical shifts (δ_{C}) are quoted in ppm, referenced to the appropriate residual solvent peak. Degenerate peaks are suffixed by the number of carbons. Chiral HPLC assays were conducted on an Agilent 1100 Series Liquid Chromatograph using a ChiralcelX-Bridge column (particle size: 3 μm ; dimensions: 4.6 \times 250 mm; Lot No. OZ30CE-PL009). All starting materials, additional reagents, solvents, and deuterated solvents for NMR spectra were obtained commercially and used without further purification.

2. CryoFree NMR Spectroscopy

The HTS NMR instrument has several components. The magnet is a high temperature superconducting (HTS) magnet (MR 9T4-54, iron-yoke NMR magnet) supplied by HTS-110 (Lower Hutt, New Zealand) and operating at 9.40 T (400.32 MHz for ¹H observation). The magnet always operates in the driven mode with current regulated by a high-stability power supply (Danfysik System 8500 model 854, Taastrup, Denmark). The cooling of the magnet is achieved by a Cryomech PT807 (Syracuse, NY, USA) pulse-tube cooler with a Cryomech CP2800 helium compressor. An air-cooled chiller (Huber Unichiller 040T, Offenburg, Germany) provides water cooling to the power supply. The shims used in the HTS magnet are passive ferromagnetic shims instead of the typical active superconducting shims found in standard commercial cryogen-bath magnets. The NMR console is an AVANCE III HD NMR (Bruker BioSpin, Billerica, MA, USA). The probe is a 5 mm Bruker multinuclear broadband fluorine observe (BBFO) (¹H on outer coil, inner coil tunable from ¹⁰⁹Ag – ¹⁹F, coil length 24 mm). Additionally, the conventional NMR system was fitted with a BCU-II preconditioner to cool the incoming sample temperature control gas, allowing operation at, below or above room temperature. The shimstack is a Bruker orthogonal shim system-3 (BOSS3) with 38 shims. Additional information on this NMR system can be found in two previous publications with details of electrical requirements and foot-print of the instrument.^{1,2}

The reaction was carried out in a capped 5 mm OD outer reaction sample tube (New Era Enterprises, Inc., part numbers NE-377-ORT and NE-377-SC, Vineland NJ, USA) at 83 °C. Two alternating measurements were acquired over a period of up to 16 hr. These were a 1D ¹H NMR (4 scans with 1 s delay and 30° pulse angle) and a 1D ¹⁹F NMR with inverse gated ¹H decoupling (16 scans with 1 s delay and 90° pulse angle). The system was set to start acquiring NMR data in automation mode, including solvent selection, probe matching/tuning, shimming, and data acquisition using InsightMR software (version 1.1.3, Bruker Biospin, Billerica, MA, USA). The processing of the data was performed with Mnova (version 14) software package (Mestrelab Research, SL, Santiago de Compostela, Spain).

3. Reaction Progress Kinetic Analysis (RPKA) and Variable Time Normalization Analysis (VTNA)

Experimental Design was conducted as described by Blackmond.^{3,4} Variable Time Normalization Analysis (VTNA) was conducted as described by Bures.⁵⁻⁸

Sample Preparation

A sample of nitrotoluene **1** (at appropriate concentration in AcOD-*d*₄) was used to conduct shimming at 83 °C. Reactions were initiated by inserting an NMR tube containing all reaction components into the pre-heated spectrometer. It was demonstrated that no reaction/decomposition occurs at RT.

Calculation of Concentration

The concentration of each species was calculated *via* absolute integration relative to the known concentration of nitrotoluene **1** at t₀ using ¹⁹F spectroscopy. The concentration of fluorinated species (nitrotoluene **1**, monobromide **2**, dibromide **3** and SM derived impurities) were determined using ¹⁹F NMR spectroscopy. NBS and succinimide concentration were determined using ¹H spectroscopy using nitrotoluene **1** as internal standard from its known concentration in the corresponding ¹⁹F spectra. The integral ranges analyzed for each species are shown below.

Table S1 – Chemical Shifts Integrated for Reaction Progress

VTNA was used to determine the order in benzoyl peroxide by calculating the decreasing concentration of benzoyl peroxide during reaction progress.⁶ Benzoyl peroxide concentration was calculated using first order decay with a $t_{1/2} = 3$ h at 83 °C.

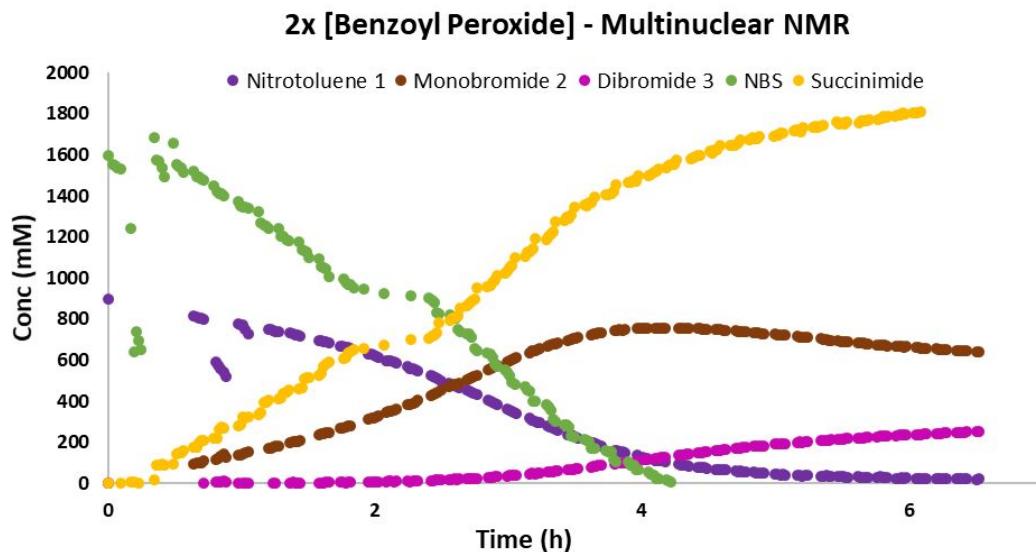

Figure S4 – Reaction Progress data for 2 x [benzoyl peroxide]

VTNA was used to determine the order in benzoyl peroxide by calculating the decreasing concentration of benzoyl peroxide during reaction progress.⁶ Benzoyl peroxide concentration was calculated using first order decay with a $t_{\frac{1}{2}} = 3$ h at 83 °C.

4. Reaction Progress Kinetic Modelling

DynoChem[®] software from Scale-Up Systems (Build: 1.3.20b340, Data Version: 1.0) was used for reaction modeling.

4.1 Simple Batch Kinetic Model

The ‘All-In’ Batch model was created using DynoChem[®] ‘Simple Batch Reaction’ model template.

Fitting was conducted with the Levenberg-Marquardt fitting algorithm using Weighted SSQ. Initially, the ‘standard reaction’ in Section 3 was included for fitting followed by refining with the other experiments and data described in Section 3. The order in monotoluene **1** set as 1.3 and benzoyl peroxide as 0.6. The radical propagation mechanism described by Goldfinger was utilized for creation of the model and extra terms to account for loss of bromine to the gas phase in a closed system added (Br sink).

HBr + NBS	→	Br ₂ + Succ.	4.43 × 10 ⁻³ L mol ⁻¹ s ⁻¹	± 22.4%
(BzO) ₂	→	2 BzO [•]	1.31 × 10 ⁻⁵ s ⁻¹ (n = 0.6)	± 20.3%
BzO [•] + Br ₂	→	Br [•] + BzOH	29.98 L mol ⁻¹ s ⁻¹	± 13.1%
SM 1 + Br [•]	→	SM 1 [•] + HBr	8.89 L mol ⁻¹ s ⁻¹ (n = 1.3)	± 12.6%
SM 1 [•] + Br ₂	→	MonoBr 2 + Br [•]	12.86 L mol ⁻¹ s ⁻¹	± 13.1%
MonoBr 2 + Br [•]	→	MonoBr 2 [•] + HBr	1.47 L mol ⁻¹ s ⁻¹	± 12.6%
MonoBr 2 [•] + Br ₂	→	Dibromide 3 + Br [•]	3.54 L mol ⁻¹ s ⁻¹	± 13.1%
2 Br ₂	→	Br sink	26.39 L mol ⁻¹ s ⁻¹	± 16.2%
Br sink	→	2 Br ₂	2.99 × 10 ⁻⁵ L mol ⁻¹ s ⁻¹	± 12.8%
Br [•] + BzOH	→	BzOH + HBr	4.34 L mol ⁻¹ s ⁻¹	± 12.6%

These reaction rates and orders were then used to predict reaction progress under ‘standard reaction’ conditions in an ‘All-In’ experiment. Comparison of the experimental data the modelled data is shown below (**Figure S5, Table S12**).

4.2 – Continuous Addition of N-Bromosuccinimide

4.2.1 - General Procedure for Continuous NBS Addition

Nitrotoluene **1** (30 g or 265 g) was loaded into a ChemGlass[®] reactor (500 mL or 5 L) followed by AcOH (2 V, 60 mL or 530 mL). Benzoyl peroxide (3 mol%) was added via an addition funnel. The reaction mixture was then heated to 83 °C over 1 h. In a separate vessel, NBS (See **Table S8** for equivalents) was stirred vigorously at room temperature as a slurry in AcOH (3.5 V; 105 mL or 930 mL).

As the nitrotoluene solution approached 83 °C, transfer of NBS slurry to the nitrotoluene solution was initiated. Slurry transfer was achieved using a Masterflex[®] peristaltic pump with Viton[®] tubing.

Reaction progress was monitored using ¹⁹F and ¹H NMR analysis.

4.2.2 – Continuous Addition Kinetic Model and Experimental Data

The continuous addition kinetic model was created using DynoChem[®] ‘Fed Batch Reaction’ model template. The reaction rates determined from the All-In RPKA experiments (**Section 3**) and DynoChem[®] modelling of the Goldfinger radical propagation mechanism (**Section 4.1**) were used to predict reaction progress under a variety of continuous addition scenarios (**Table S8**). Experimental data is included below and modelled data obtained from the DynoChem[®] model. For simulations, 1000 points were calculated using the Rosenbrock Intergration with an accuracy of 1×10^{-3} .

It should be noted that as the total volume of the reaction mixture is continually changing during continuous addition, absolute concentration is not an appropriate measurement from which to determine reaction progress. For experimental / modelled data reported using continuous addition mode, *total moles* present in either the Batch or Feed are reported.

Total moles of Nitrotoluene **1**, Monobromide **2** and Dibromide **3** were determined by conversion using ¹⁹F NMR using known starting concentration of nitrotoluene **1** as reference.

6. Minimization of NBS Equivalents

DynoChem[®] optimization function was used to minimize the equivalents of NBS used in continuous addition mode whilst ensuring end of reaction specifications were met.

Model variables, specification and end of reaction target are described below (**Table S16**).

Table S21 – Specifications for NBS minimization

Variable	Range	Initial Value
NBS Equivalents	0.1 – 1.0 mol	0.1 mol
Reaction Specifications		
Nitrotoluene 1	0.193 moles	
NBS Addition Time	300 min	
End of Reaction Time	480 min	
Target		
Conversion	92 mol%	

Optimization was complete within 24 iterations and determined 0.2512 moles of NBS would be required to achieve a yield of > 92% for continuous addition using 0.193 nitrotoluene **1** (**Table S17**). This corresponds to 1.30 equivalents of NBS relative to nitrotoluene **1**.

7. Estimation of Benzoyl Peroxide Half Life

For VTNA analysis of benzoyl peroxide as a initiator of constantly decreasing concentration an approximate value of the half life was required (See **Sections 3.1 and 3.4**). This value was obtained from *Sanchez and Myers¹⁰* reported data and calculated for 83 °C as shown in **Figure S12**. A value of $T_{1/2} = 3$ h was utilized for VTNA studies.
